b-flavour tagging in pp collisions

Alex Birnkraut on behalf of the LHCb collaboration

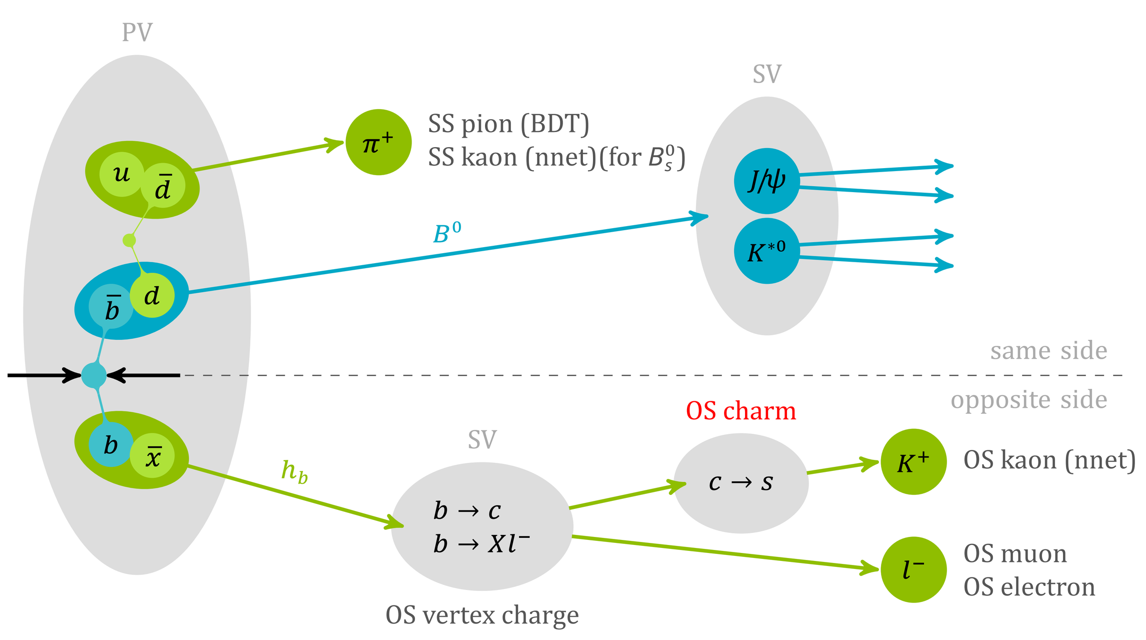
Basics

Introduction

Measurements of flavour oscillations and time-dependent CP asymmetries in neutral B meson systems require knowledge of the b quark flavour at production. This identification is performed by the Flavour Tagging. [1,2]

Two independent classes of algorithms

- **same side taggers (SS)**
  use charged particles created in the fragmentation process of the b quark of the signal B meson
  - kaon for B_s^0 $\rightarrow$ SS kaon / SS kaon nnet
  - pion for B^0 $\rightarrow$ SS pion / SS pion BDT
  - proton for B^0 $\rightarrow$ SS proton
- **opposite side taggers (OS)**
  exploit the non-signal b quark of the initial $b\bar{b}$ pair
  - overall charge of the secondary vertex (SV) $\rightarrow$ OS vertex charge
  - lepton from semi-leptonic b hadron decays $\rightarrow$ OS muon / OS electron
  - kaon from the $b \rightarrow c \rightarrow s$ decay chain $\rightarrow$ OS kaon / OS kaon nnet
  - D meson from the $b \rightarrow c$ decay chain $\rightarrow$ OS charm



Each tagger provides a decision d on the initial flavour ("tag") and a probability to be wrong, η.

Flavour Tagging characteristics

- **mistag**
  fraction of events with a wrong tagging decision
  $$\omega = \frac{N_{\text{wrong}}}{N_{\text{right}} + N_{\text{wrong}}}$$
- **tagging efficiency**
  fraction of events with a tagging decision
  $$\varepsilon_{\text{tag}} = \frac{N_{\text{right}} + N_{\text{wrong}}}{N_{\text{all}}}$$
- **effective tagging efficiency**
  represents the statistical reduction factor of a sample in a tagged analysis
  $$\varepsilon_{\text{eff}} = \varepsilon_{\text{tag}}\,(1 - 2\omega)^2$$

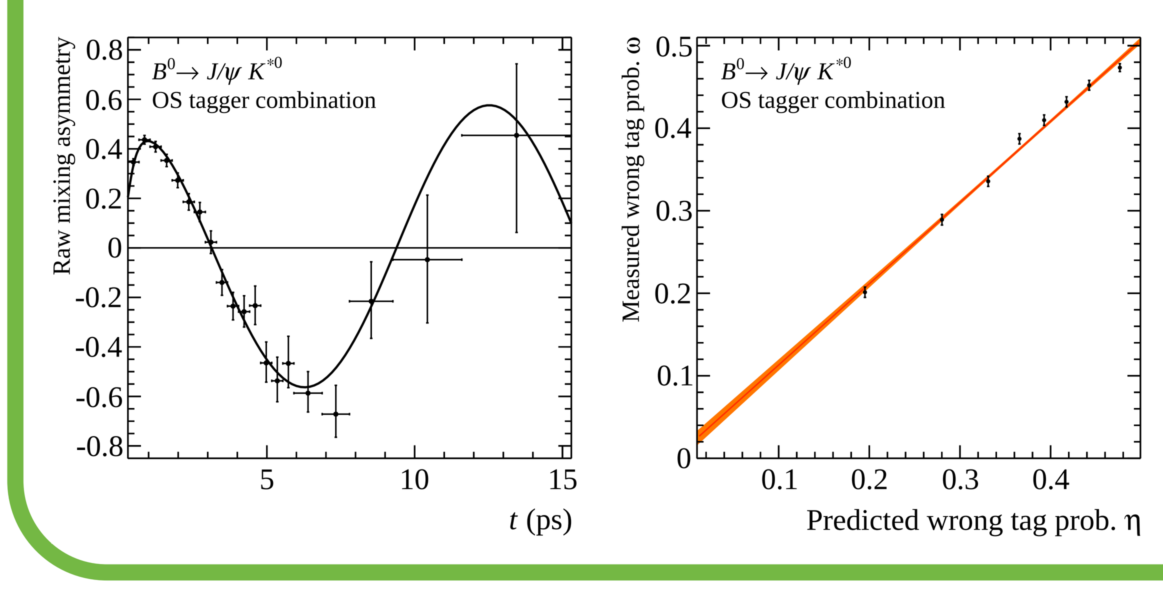
Calibration

Mistag calibration

$$\underset{\substack{\text{measured}\\ \text{ev-by-ev mistag}}}{\omega(\eta)} = p_0 + \underset{\substack{\text{estimated}\\ \text{ev-by-ev mistag}}}{p_1(\eta} - \underset{\substack{\text{mean}\\ \text{estimated mistag}}}{\langle\eta\rangle)}$$

Several flavour-specific decay channels are used

- $B^+ \rightarrow J/\psi K^+$, $B^+ \rightarrow D^0\pi^+$
  charged channels: extract ω by comparing tag decision with charge of the final state
- $B^0 \rightarrow J/\psi K^{*0}$, $B^0 \rightarrow D^{*-}\mu^+\nu_\mu$, $B_s^0 \rightarrow D_s^-\pi^+$, ...
  neutral channels: full time-dependent analysis to extract ω from the mixing asymmetry
  $$\mathcal{A}_{\text{mix}}(t) \propto (1 - 2\omega)\cos(\Delta m_{d/s} t)$$



Flavour Tagging in Run I

Strategy

- for each tagger one calibration valid for all channels
- systematic uncertainties from
  - calibration methods
  - results in different control channels
- "ad-hoc" calibration from specific control channels for analyses dominated by FT uncertainty

Performance in analyses

$B^0 \rightarrow J/\psi\,\pi^+\pi^-$	-	3.26		*Phys. Lett. B* 742 (2015) 38-49

Performance improvements in Run I

- OS tagging improved $\mathcal{O}(15\%)$
- SS kaon tagging improved $\mathcal{O}(40\%)$

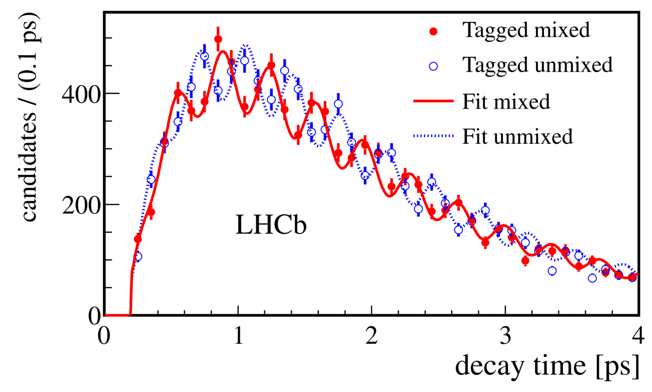
$\Rightarrow$ **Flavour Tagging has been a success in Run I**

Highlight analyses using flavour tagging

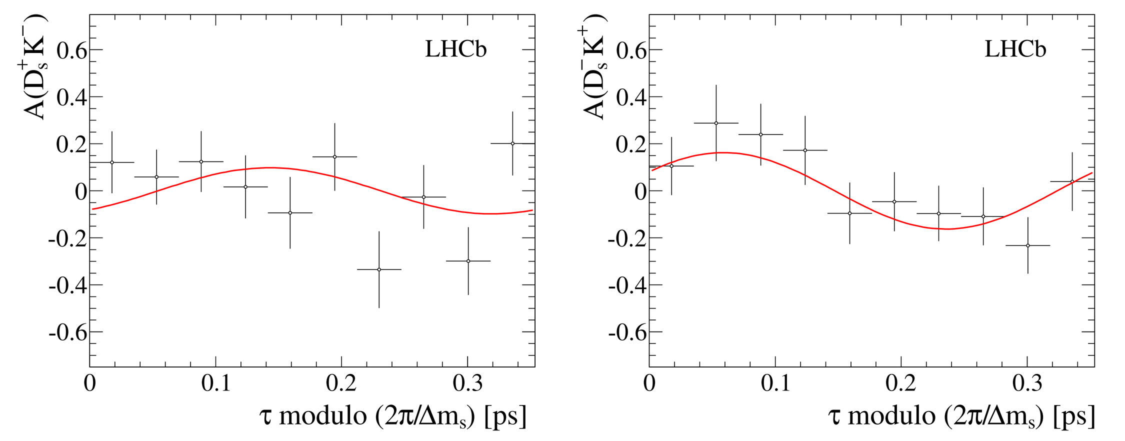
Measurement of Δm_s

Determination of the $B_s^0 - \bar{B}_s^0$ oscillation frequency with $B_s^0 \rightarrow D_s^-\pi^+$ [3].

$e^{-\Gamma t}\,(\ldots + d\cos(\Delta m t))$



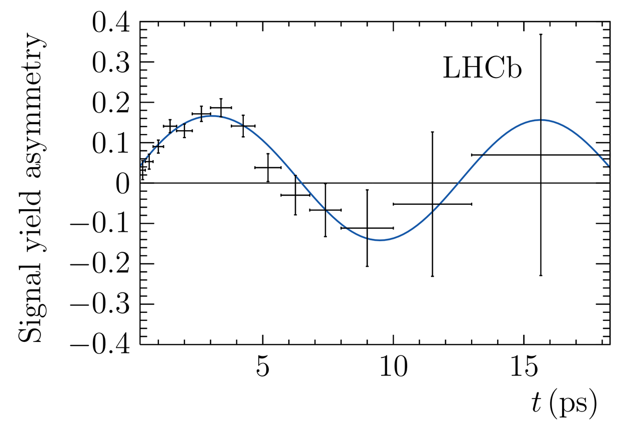
Measurement of CP ciolation in $B_s^0 \rightarrow D_s^{\mp}K^{\pm}$ decays



$\rightarrow$ SS kaon nnet adds more than 1.3 % to ε_{eff} [4]

Measurement of $\sin 2\beta$

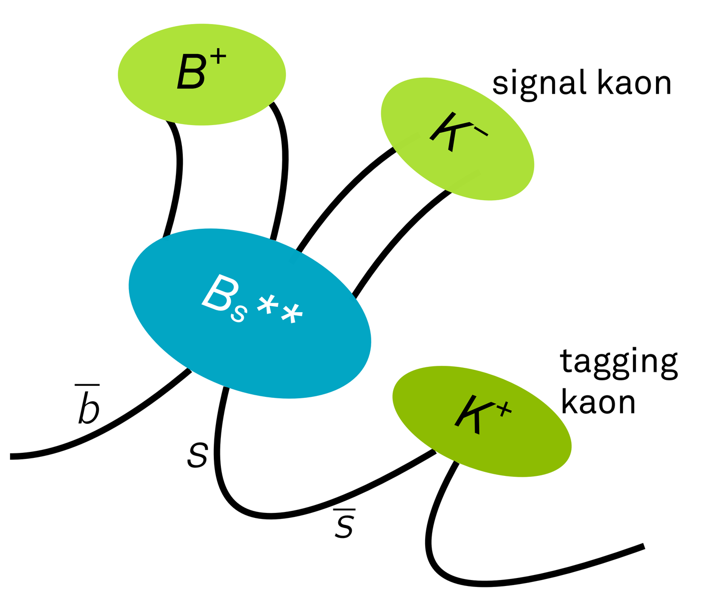
$\rightarrow$ precision analysis
$\rightarrow$ "ad-hoc" calibration with $B^+ \rightarrow J/\psi K^+$ and $B^0 \rightarrow J/\psi K^{*0}$ [5]



Developments

SS kaon calibration with excited B_s^0 states

- SS kaon taggers calibrated with $B_s^0 \rightarrow D_s^-\pi^+$ only
  - limited statistics
  - time-dependent analysis required
- new idea: calibrate with B_s^{**0} decays
  - narrow states
  - reconstruct in $B_s^{**0} \rightarrow B^+K^-$ decays
  - calibrate by counting, as in other charged modes



- true independent crosscheck for $B_s^0 \rightarrow D_s^-\pi^+$
- results in agreement with $B_s^0 \rightarrow D_s^-\pi^+$ channel

SS pion calibration

- calibration performed with $B^0 \rightarrow J/\psi K^{*0}$
- full evaluation of systematic uncertainties
- used for the first time in the measurements of
  - $\sin(2\beta)$ with $B^0 \rightarrow J/\psi K_S^0$
    - $\Rightarrow$ precision comparable to B-factories
    - $\Rightarrow$ $\varepsilon_{\text{eff}}^{\text{SS}\pi} = 0.38\,\%$
  - $\sin(2\beta_{\text{eff}})$ with $B^0 \rightarrow J/\psi\pi^+\pi^-$
    - $\Rightarrow$ $\varepsilon_{\text{eff}}^{\text{SS}\pi} = 0.54\,\%$

OS and SS Kaon tagging using neural nets (NN)

- basic idea: use two NN
  - first NN distinguishes between:
    1. fragmentation tracks
       $\Rightarrow$ signal for SS kaon nnet
    2. OS b hadron tracks
       $\Rightarrow$ signal for OS kaon nnet
    3. underlying event tracks

  - second NN:
    - receives up to 3 candidates
    - assigns final tag and mistag
- SS kaon nnet tagger is a great success, compared to the previous cut-based SS kaon it gives
  - $B_s^0 \rightarrow D_s^-\pi^+$: 50 % relative improvement in ε_{eff}
  - $B_s^0 \rightarrow J/\psi\phi$: 41 % relative improvement in ε_{eff}

OS charm tagger

- reconstruct $D^0/D^{\pm}/D^*$ decays related to OS b decay
- one boosted decision tree (BDT) for each mode
- clean measure of B meson flavour (low mistag)
- adds about 0.37 % to ϵ_{eff}

SS pion BDT and SS proton

- promising new taggers based on BDT's
- development ongoing
